

PHYS 632: Quantum Mechanics II (Winter 2021)
Exercises 4 January 2021 (Monday, Week 1)
Due Monday, 11 January 2021

Exercise 1. A classic and simple example of the saddle-point approximation is the derivation of Stirling's approximation for $n!$. To set this up, recall the integral representation for the gamma function,

$$\Gamma(x) = \int_0^\infty dt t^{x-1} e^{-t}, \quad (1)$$

and since $n! = \Gamma(n+1)$, we have

$$n! = \int_0^\infty dt t^n e^{-t} = \int_0^\infty dt e^{-t+n \log t}. \quad (2)$$

(a) Now the idea is to approximate the integrand by a Gaussian factor, which is valid because the integrand becomes sharply peaked as n becomes large. To do this, write the integrand as $e^{f(t)}$, and expand $f(t)$ to second order in t about the maximum to write

$$n! \approx e^{-n+n \log n} \int_0^\infty dt e^{-(t-n)^2/2n}. \quad (3)$$

(b) Now to finish the integration, since the integrand is sharply peaked far away from $t=0$, we can extend the lower integration limit so that

$$n! \approx e^{-n+n \log n} \int_{-\infty}^\infty dt e^{-(t-n)^2/2n}. \quad (4)$$

Now carry out the integral to find Stirling's approximation,

$$n! \approx \sqrt{2\pi n} \left(\frac{n}{e}\right)^n. \quad (5)$$

a)

$$e^{-t+n \log t}$$

$$f(t) = n \log t - t$$

$$f(n) = n \log n - n$$

$$f'(n) = 0$$

$$f''(n) = -\frac{1}{n}$$

$$f(t) \approx n \log n - n - \frac{1}{2n} (t-n)^2$$

$$\rightarrow n! \approx e^{-n+n \log n} \int_0^{\infty} dt e^{-(t-n)^2/2n}$$

$$b) \quad n! \approx e^{-n+n \log n} \int_{-\infty}^{\infty} e^{-(t-n)^2/2n} dt$$

$$= e^{-n+n \log n} \sqrt{2n\pi}$$

$$\rightarrow n! \approx \sqrt{2\pi n} e^{-n} n^n$$

$$\text{from } \int_{-\infty}^{\infty} e^{-ax^2} dx = \sqrt{\frac{\pi}{a}}$$
